

Lecture 2 Monoidal cuts I - Defs, Examples + graphs¹

What are the **correct axioms** to get a **planar** graphical calculus?

$$X_1 \otimes X_2 \rightsquigarrow X_1 \uparrow \uparrow X_2 \quad f: X_1 \otimes X_2 \otimes X_3 \rightarrow Y_1 \otimes Y_2$$

$$f \otimes g \rightsquigarrow \begin{array}{c} \uparrow \\ \textcircled{f} \\ \uparrow \end{array} \begin{array}{c} \uparrow \\ \textcircled{g} \\ \uparrow \end{array}$$

Respecting \uparrow :

OK $\begin{array}{c} \uparrow \\ \textcircled{f} \\ \uparrow \end{array} \begin{array}{c} \uparrow \\ \textcircled{g} \\ \uparrow \end{array} = \begin{array}{c} \uparrow \\ \textcircled{f} \\ \uparrow \end{array} \begin{array}{c} \uparrow \\ \textcircled{g} \\ \uparrow \end{array}$

Bad $\begin{array}{c} \textcircled{f} \\ \textcircled{j} \quad \textcircled{g} \\ \textcircled{R} \end{array} \begin{array}{c} \uparrow \\ \textcircled{i} \\ \uparrow \end{array} = \begin{array}{c} \textcircled{f} \\ \textcircled{g} \\ \textcircled{R} \end{array} \begin{array}{c} \uparrow \\ \textcircled{i} \\ \uparrow \end{array}$

$\mathcal{C} \times \mathcal{C} \leadsto$ cat with objects (X, Y) morph. (f, g) 2

Motivating example

$$\otimes : \text{Set} \times \text{Set} \rightarrow \text{Set}$$

$$(x, y) \mapsto x \times y =: X \otimes Y$$

Note: $\{ \cdot \} = \mathbb{1}$ is a unit object i.e. $\mathbb{1} \otimes X \underset{\neq}{\simeq} X \underset{\neq}{\simeq} X \otimes \mathbb{1}$

- This is only *weakly* associative, i.e.

$$(X \otimes Y) \otimes Z \underset{\neq}{\simeq} X \otimes (Y \otimes Z)$$

$$((x, y), z) \quad \neq \quad (x, (y, z))$$

- Also the unit is only *weak* $(\cdot, x) \neq x \neq (x, \cdot)$

Def 2.1 A **monoidal cat** $\mathcal{C} = (\mathcal{C}, \otimes, \mathbb{1}, \alpha, \ell, \nu)$ consist of

- a category \mathcal{C}
- a bifunctor $\otimes : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C}$
- a unit $\mathbb{1}$
- natural iso $\alpha_{X,Y,Z} : (X \otimes Y) \otimes Z \xrightarrow{\sim} X \otimes (Y \otimes Z)$

called **associator**

- natural iso $\ell_x : \mathbb{1} \otimes X \xrightarrow{\sim} X$
- natural iso $\nu_x : X \otimes \mathbb{1} \xrightarrow{\sim} X$

called **unitors**

Recall: naturally means that a \square -commutes

such that \square -equation and the Δ -equation hold. (I.e. commute)

$$id_X \otimes id_Y = id_{X \otimes Y}$$

$$(k \otimes h) \circ (g \otimes f) = (k \circ g) \otimes (h \circ f)$$

△
"Unit"

$$(X \otimes \mathbb{1}) \otimes Y \xrightarrow{\alpha_{X, \mathbb{1}, Y}} X \otimes (\mathbb{1} \otimes Y)$$

$$\downarrow \alpha_{X \otimes \mathbb{1}, Y} \quad \downarrow \text{id} \otimes \alpha_{\mathbb{1}, Y}$$

$$X \otimes Y \longleftarrow X \otimes Y$$

□

$$(U \otimes V) \otimes W \xrightarrow{f \otimes g \otimes h} (X \otimes Y) \otimes Z$$

$$\downarrow \alpha_{U, V, W} \quad \downarrow \alpha_{X, Y, Z}$$

$$U \otimes V \otimes W \xrightarrow{f \otimes (g \otimes h)} X \otimes (Y \otimes Z)$$

From now on
 $XY := X \otimes Y$

"Assoc"

$$((W \otimes X) \otimes Y) \otimes Z$$

$$\swarrow \alpha_{W \otimes X, Y, Z} \quad \searrow \alpha_{W, X, Y} \otimes \text{id}$$

$$(W \otimes X) \otimes (Y \otimes Z) \quad (W \otimes (X \otimes Y)) \otimes Z$$

$$\downarrow \alpha_{W, X, Y \otimes Z} \quad \downarrow \alpha_{W, X \otimes Y, Z}$$

$$W \otimes (X \otimes (Y \otimes Z)) \xleftarrow{\text{id} \otimes \alpha_{X, Y, Z}} W \otimes ((X \otimes Y) \otimes Z)$$

Why is this a bad Definition?

Wrong def / monoid

Correct def / monoid

- A set M

- Same

- multiplication $\cdot : M \times M \rightarrow M$

- Same

- unit $1 \in M$

- Same

- asso $(k \cdot m) \cdot n = k \cdot (m \cdot n)$

- asso: all bracketings are the same

Note: $(k \cdot m) \cdot n = k \cdot (m \cdot n)$ is not associativity, but it is so well-known that

wrong \Rightarrow correct

that this is usually ignored...

Theorem 2.2 (Coherence)

All ways to build associators and unitors are the same

Proof (Sketch)

Let analyze the 1-dim case: ← "monoids"

Or said otherwise, the 1-dim CW complex K_1 which one gets by adding an edge for each (*) is connected i.e. $\pi_0(K_1) = 1$

← "graph"

Play the same game:

7

K_3

K_4

K_5

Then $\pi_1(K_n) = 1$ implies coherence. Similar for unitons.

Def 2.3 \mathcal{L} is called *strict* if α, β, γ are all identities

Examples - Set with $\otimes = \times$, $\perp = \{\cdot\}$ *non-strict*

- Set with $\otimes = +$ (*dis. union*), $\perp = \emptyset$ *non-strict*

- $\text{Vect}_{\mathbb{K}}$ with $\otimes = \otimes_{\mathbb{K}}$, $\perp = \mathbb{K}$ *non-strict*

- $\text{Vect}_{\mathbb{K}}$ with $\otimes = \oplus$, $\perp = \{0\}$ *non-strict*

(Note that their skeletons are strict)

- 1 Col, 1 Tan, 1 State *strict*

$\otimes = \text{juxtaposition}$, $\perp = \emptyset$

- Groups / Monoids as \otimes -cats

$\text{Vect}(M)$ Ob = elements of M

Mor = only $1K$ -id

$m \otimes n = m \cdot n$

$\underline{11} = 1$

strict

\exists counit
 $w: M \times M \times M \rightarrow 1K^*$
 satisfying the
 \square -axiom

- $\text{Vect}^w(M)$ same but

$\alpha = \exists$ counit
 $l = \alpha(1, 1, m)^{-1}$
 $r = \alpha(m, 1, 1)$

Example: $M = \mathbb{Z}/2 = \langle 1, \sigma \rangle$
 $\alpha = 1$ except $\alpha(\sigma, \sigma, \sigma) = -1$

non-strict $w \neq 1$, and skeletal

Question Can we ignore α, ℓ, ν , i.e. is every \mathcal{L} ¹⁰
"stratifiable"?

The last example shows that one *can not* simply go to the skeleton.

However, the answer is "Yes" as we will see.

In particular, we will usually ignore α, ℓ, ν and work with strict \otimes -cats.

First things first:

Def 2.4 A \otimes -functor $F: \mathcal{C} \rightarrow \mathcal{C}'$ consists of:

- a functor F
- natural isomorphisms

$$\xi_{X,Y}: F(X) \otimes' F(Y) \xrightarrow{\sim} F(X \otimes Y)$$

- natural isomorphism $\xi_I: \mathbb{1}' \xrightarrow{\sim} F(\mathbb{1})$

Such that one has commutative diagrams

$$\begin{array}{ccccc} (F(X) \otimes' F(Y)) \otimes' F(Z) & \xrightarrow{\xi \otimes \text{id}} & F(X \otimes Y) \otimes' F(Z) & \xrightarrow{\xi} & F((X \otimes Y) \otimes Z) \\ \alpha' \downarrow & & & & \downarrow F(\alpha) \\ F(X) \otimes' (F(Y) \otimes' F(Z)) & \xrightarrow{\text{id} \otimes \xi} & F(X) \otimes' F(Y \otimes Z) & \xrightarrow{\xi} & F(X \otimes (Y \otimes Z)) \end{array}$$

hexagon-equation

\square -equation

$$\begin{array}{ccc} I' \otimes F(X) & \xrightarrow{\xi_0 \otimes \text{id}} & F(I) \otimes' F(X) \\ \downarrow \lambda' & & \downarrow \xi \\ F(X) & \xleftarrow{F(\lambda)} & F(I \otimes X) \end{array} \quad \text{and} \quad \begin{array}{ccc} F(X) \otimes I' & \xrightarrow{\text{id} \otimes \xi_0} & F(X) \otimes' F(I) \\ \downarrow \rho' & & \downarrow \xi \\ F(X) & \xleftarrow{F(\rho)} & F(X \otimes I) \end{array}$$

Def 2.5 A \otimes -nat trnfo $\varphi: \mathcal{F} \Rightarrow \mathcal{G}$ is a nat¹²
 trnfo such that

$$\varphi_{11} \{0\}^{\mathcal{F}} = \{0\}^{\mathcal{G}} \quad , \quad \varphi_{xy} \{xy\}^{\mathcal{F}} = \{xy\}^{\mathcal{G}} \varphi_x \varphi_y$$

$\mathcal{C} \simeq \mathcal{D}$ as \otimes -cats if $\exists F: \mathcal{C} \rightarrow \mathcal{D}$ which is an
equivalence and a \otimes -functor

Example - $\text{Set}_x \simeq \text{Sh}(\text{Set})_x$ as \otimes -cats

- $\text{Vect}_{\mathbb{K}} \simeq \text{Mat}_{\mathbb{K}}$ as \otimes -cats
 $\otimes_{\mathbb{K}}$ $\otimes_{\mathbb{K}}$

- $\text{Vect } M \neq \text{Vect}^w M$ as \otimes -cats in general, but always a cats.

Similarly define \otimes -subalgs etc.

13

Lemma 2.6

Composition of \otimes -functors are \otimes -functors

Composition of \otimes -nat transf are \otimes -nat transf

Theorem 2.7 Every \otimes -cat is \otimes -equi
to a strict one.

↖ No $\alpha, \rho, \nu, \theta$

Proof, sketch

Use some \otimes -version of Yoneda.

Since we can wlog assume that \mathcal{C} is strict,
we can use graphical calculus!

$$XY \rightsquigarrow X \uparrow \uparrow Y \quad f: XY \rightarrow Z$$

$$fg \rightsquigarrow \begin{array}{c} \uparrow \\ \textcircled{f} \\ \uparrow \end{array} \begin{array}{c} \uparrow \\ \textcircled{g} \\ \uparrow \end{array}$$

Rules: Plura isotopies (*)
respecting \uparrow .

Theorem 2.8

The graphical calculus is consistent, i.e.
two morphisms are the same iff their graphical repr.
are related by a (*) isotopy.

To wrap up, let me do some proofs using ¹⁵ graphical calculus.

First, note that $\text{End}_{\mathcal{C}}(\mathbb{1}) = \text{Hom}_{\mathcal{C}}(\mathbb{1}, \mathbb{1})$ is a monoid.

Proposition 2.9

$\text{End}_{\mathcal{C}}(\mathbb{1})$ is commutative

Proof

$$\begin{array}{c} \textcircled{g} \\ \textcircled{f} \end{array} = \begin{array}{c} \textcircled{f} \\ \textcircled{g} \end{array} = \begin{array}{c} \textcircled{g} \\ \textcircled{f} \end{array} = \begin{array}{c} \textcircled{f} \\ \textcircled{g} \end{array}$$

Proposition 2.10

We have two commuting actions

$$\text{End}_\mathbb{C}(\mathbb{1}) \curvearrowright \text{Hom}_\mathbb{C}(X, Y) \curvearrowright \text{End}_\mathbb{C}(\mathbb{1})$$

Thus, $\text{Hom}_\mathbb{C}(X, Y)$ is a $\text{End}_\mathbb{C}(\mathbb{1})$ bimodule

Proof:  = some morphism in $\text{Hom}_\mathbb{C}(X, Y)$

$$\begin{aligned} \textcircled{p} \left(\begin{array}{c} \uparrow Y \\ \text{---} \\ \downarrow X \end{array} \right) \textcircled{g} &= \textcircled{p} \left(\begin{array}{c} \uparrow Y \\ \text{---} \\ \downarrow X \end{array} \right) \textcircled{g} \\ \textcircled{g} \left(\textcircled{p} \left(\begin{array}{c} \uparrow Y \\ \text{---} \\ \downarrow X \end{array} \right) \right) &= \textcircled{g} \textcircled{p} \left(\begin{array}{c} \uparrow Y \\ \text{---} \\ \downarrow X \end{array} \right) + \text{mirror} \end{aligned}$$

Proposition 2.11

The actions of $\text{End}_c(\mathbb{1})$ on $\text{Hom}_c(X, Y)$ are compatible with \circ and \otimes .

Proof
