

What is...spectral Hamiltonicity?

Or: The second largest - part 3

Hamiltonian graphs

-
- ▶ **Hamiltonian cycle** = a cycle that visits every vertex exactly once
 - ▶ **Hamiltonian graph** = a graph with an Hamiltonian cycle
 - ▶ **Question** How can we check whether a graph Hamiltonian?

Very difficult

BRUTE-FORCE
SOLUTION:

$$O(n!)$$

DYNAMIC
PROGRAMMING
ALGORITHMS:

$$O(n^2 2^n)$$

SELLING ON EBAY:

$$O(1)$$

STILL WORKING
ON YOUR ROUTE?

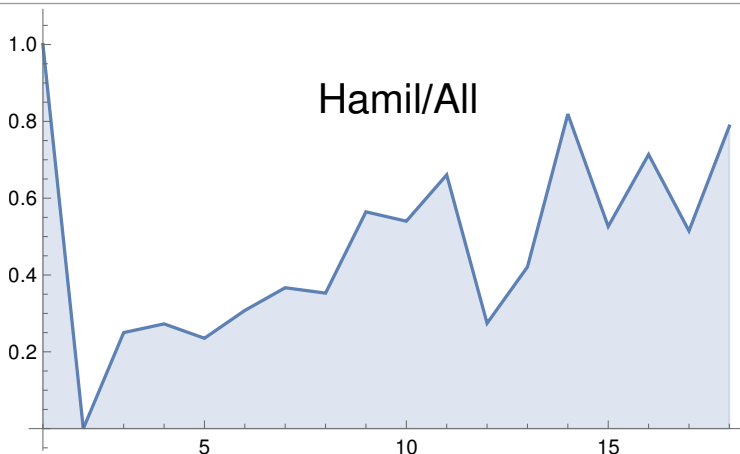

SHUT THE
HELL UP.

(This is the traveling salesperson problem.)

- ▶ Hamiltonian graph was one of the first problems shown to be NP-complete
- ▶ NP-complete “=” can't do much better than brute force
- ▶ Dynamic programming algorithms solves this is roughly in $O(n^2 2^n)$, $n = \#V$

But almost all graphs are Hamiltonian!

- ▶ To determine **precisely** whether a graph is Hamiltonian is difficult
- ▶ To determine **approximately** whether a graph is Hamiltonian is easy
- ▶ **Idea** Maybe the spectrum helps to prove Hamiltonian for large enough graphs

For completeness: A formal statement

For a k -regular graph with n vertices and

$$\lambda_2/\lambda_1 < \frac{(\log \log n)^2}{1000 \log n \log \log \log n}$$

is Hamiltonian

- $\frac{(\log \log n)^2}{1000 \log n \log \log \log n}$ goes to zero but very slowly :

- It follows that every sufficiently large strongly regular graph is Hamiltonian

λ_2 is rather small

► “Very often” $\lambda_2 < 2\sqrt{\lambda_1 - 1} + \varepsilon$

► Thus, λ_2 is “very often” tiny compared to λ_1

► Checking e.g. $\lambda_2/\lambda_1 < 2/n^{1/10}$ for some graphs then implies that they are Hamiltonian

Thank you for your attention!

I hope that was of some help.
